1 Functions for Barzilai-Borwein Optimization

The functions in this package are made available with

```
> library("BB")
```

The package setRNG is not necessary, but if you want to exactly reproduce the examples in this guide then do this:

These examples are from La Cruz and Raydan, Optim Methods and Software 2003, 18 (583-599).

```
> expo1 <- function(x) {
      n \leftarrow length(x)
      f \leftarrow rep(NA, n)
      f[1] \leftarrow \exp(x[1] - 1) - 1
      f[2:n] \leftarrow (2:n) * (exp(x[2:n] - 1) - x[2:n])
> p0 <- runif(100)
> sane(par = p0, fn = expo1)
> dfsane(par = p0, fn = expo1)
> expo3 <- function(p) {</pre>
      n <- length(p)</pre>
       f \leftarrow rep(NA, n)
       onm1 <- 1: (n - 1)
       f[onm1] \leftarrow onm1/10 * (1 - p[onm1]^2 - exp(-p[onm1]^2))
      f[n] \leftarrow n/10 * (1 - exp(-p[n]^2))
  }
> n <- 100
> p0 <- (1:n)/(4 * n^2)
> sane(par = p0, fn = expo3)
> dfsane(par = p0, fn = expo3)
```

This example is from Freudenstein and Roth function (Broyden, Mathematics of Computation 1965, p. 577-593)

```
> froth <- function(p) {
    f <- rep(NA, length(p))
    f[1] <- -13 + p[1] + (p[2] * (5 - p[2]) - 2) * p[2]
    f[2] <- -29 + p[1] + (p[2] * (1 + p[2]) - 14) * p[2]
    f
}</pre>
```

Here p0 gives the zero of the system

```
> p0 \leftarrow c(3, 2)
> same(par = p0, fn = froth)
> dfsane(par = p0, fn = froth)
   Here p0 gives the local minimum that is not the zero of the system.
> p0 \leftarrow c(1, 1)
> sane(par = p0, fn = froth)
> dfsane(par = p0, fn = froth)
   Trying random starts
> p0 <- rpois(2, 10)
> sane(par = p0, fn = froth)
> dfsane(par = p0, fn = froth)
   This example is from
> trig <- function(x) {</pre>
      n \leftarrow length(x)
      suma \leftarrow sum(cos(x))
      o2n <- 1:n
      F \leftarrow 2 * (n + o2n * (1 - cos(x)) - sin(x) - sum(cos(x))) *
           (2 * sin(x) - cos(x))
  }
> p0 <- runif(100)
> same(par = p0, fn = trig)
> dfsane(par = p0, fn = trig)
   This example is from
> trigexp <- function(x) {</pre>
      n \leftarrow length(x)
      F \leftarrow rep(NA, n)
      F[1] \leftarrow 3 * x[1]^2 + 2 * x[2] - 5 + \sin(x[1] - x[2]) * \sin(x[1] + x[2])
      tn1 <- 2:(n - 1)
      F[tn1] \leftarrow -x[tn1 - 1] * exp(x[tn1 - 1] - x[tn1]) + x[tn1] *
           (4 + 3 * x[tn1]^2) + 2 * x[tn1 + 1] + sin(x[tn1] - x[tn1 +
           1]) * sin(x[tn1] + x[tn1 + 1]) - 8
      F[n] \leftarrow -x[n-1] * exp(x[n-1] - x[n]) + 4 * x[n] - 3
  }
> sane(par = p0, fn = trigexp)
> dfsane(par = p0, fn = trigexp)
```

This example is from

```
> chen <- function(x) {</pre>
       v \leftarrow log(x) + exp(x)
      f \leftarrow (v - sqrt(v^2 + 0.005))/2
  }
> sane(par = p0, fn = chen)
> dfsane(par = p0, fn = chen)
> valley <- function(x) {</pre>
       c1 <- 1.00334448160535
       c2 <- -0.000334448160535117
      n \leftarrow length(x)
       f \leftarrow rep(NA, n)
      j <- 3 * (1:(n/3))
      jm2 <- j - 2
       jm1 <- j - 1
       f[jm2] \leftarrow (c2 * x[jm2]^3 + c1 * x[jm2]) * exp(-(x[jm2]^2)/100) -
      f[jm1] \leftarrow 10 * (sin(x[jm2]) - x[jm1])
      f[j] \leftarrow 10 * (cos(x[jm2]) - x[j])
      f
  }
   Here the number of variables must be a multiple of 3
> p102 <- runif(102)
> sane(par = p102, fn = valley)
> dfsane(par = p102, fn = valley)
> broydt <- function(x) {</pre>
      n \leftarrow length(x)
       f \leftarrow rep(NA, n)
      f[1] \leftarrow ((3 - 0.5 * x[1]) * x[1]) - 2 * x[2] + 1
       tnm1 \leftarrow 2: (n - 1)
       f[tnm1] \leftarrow ((3 - 0.5 * x[tnm1]) * x[tnm1]) - x[tnm1 - 1] -
           2 * x[tnm1 + 1] + 1
       f[n] \leftarrow ((3 - 0.5 * x[n]) * x[n]) - x[n - 1] + 1
  }
> sane(par = p0, fn = broydt)
> dfsane(par = p0, fn = broydt)
```
